SIGNETICS INSTRUCTOR 50T DESKTOP COMPUTER SOFTWARE APPLICATIONS MANUAL

SIGNETICS INSTRUCTOR 50T DESKTOP COMPUTER SOFTWARE APPLICATIONS MANUAL

by

John C. Garceau

The applications contained in this manual are for illustration purposes only. SIGNETICS CORPORATION makes no representation or warranty that such applications are suitable for the use specified without further testing and modification.

INSTRUCTOR 50 is a trademark of Signetics Corporation.

<u>SIGNETICS CORPORATION</u> is a wholly-owned subsidiary of U. S. Philips Corporation.

INSTRUCTOR 50 PROGRAM APPLICATIONS

INTRODUCTION:

Originally intended as a separate part (Chapter 6) of the INSTRUC-TOR 50 INTRODUCTORY MANUAL, this manual is now released as a "standalone" document for use by INSTRUCTOR 50 owners. This manual provides a wealth of detailed information about the various programs contained in the INSTRUCTOR 50 INTRODUCTORY CASSETTE. The following outline is provided for your convenience. Use it to index quickly to any point of interest you may desire to examine.

2650 PROGRAMMING FORM(left blank for your duplication purposes)	97

NOTE:

As much as possible, these pages are designed with <u>your</u> use in mind. There's plenty of space for your notes and observations. Take $\underline{\mathsf{time}}$ to study and practice the use of the INSTRUCTOR 50 and the 2650 microprocessor which it hosts. You'll find each minute devoted to this will valuably increase your knowledge.

INTRODUCTION TO ASSEMBLERS

COMMENTARY:

When we entered information in the coding forms for examples provided in Chapter 5, we first wrote each program in MNEMONIC form. The MNEMONIC representation of a program is called assembly lanquage. Each instruction written in ASSEMBLY LANGUAGE has a corresponding HEXADECIMAL CODE which can be executed by the INSTRUCTOR
50. However, it is much easier for us as humans to interpret instructions written in assembly language rather than in hexadecimal code. Hexadecimal (HEX) code, with each digit representing 4 bits, is also known as MACHINE LANGUAGE. Once a program has been written in assembly language, it is a straight-forward task to translate it into machine language.

This translation task can be accomplished by a computer program. Such a program is called an ASSEMBLER PROGRAM. The purpose of the assembler program is to take information appearing on the right side of the CODING FORM and translate it into information for the left side of the coding form. The ASSEMBLER PROGRAM then produces a PRINTOUT which is similar to the coding form filled out in its entirety. This printout is called a LISTING of the program.

The listings for all of the programs recorded on the INSTRUCTOR 50 INTRODUCTORY CASSETTE are contained in the remainder of this chapter. Two of the listings are printouts from an assembler program run on the "TWIN", a Signetics software development system. The other listings were HANDCODED and then reproduced on the Signetics 2650 PROGRAMMING FORM.

The information which appears on the right-hand side of the coding form is called SOURCE CODE. Simply, source code is information which the assembler (or HANDCODING programmer) must have in order to generate MACHINE LANGUAGE code. The HEX-CODES for the instructions which are generated by the assembler are known also as OBJECT CODES. After all, generation of valid machine language code is the OBJECT of the assembler.

Before the assembler can produce object code, it must be provided certain key information in addition to that appearing in the right hand columns of the coding form. This information is provided in the form of DIRECTIVES. For example, if you wish the start address for a routine to be at location H'100' in memory, you would input the directive ROUT ORG H'100' to the assembler. "ROUT", in the coding form's LABEL field, defines the name of the routine. It could be any combination of letters and numbers. "ORG", in the coding form's OPCODE field, directs the assembler to recognize this as a specific start address; a PROGRAM ORIGIN! "H'100'", in the OPERAND field, defines the memory address. The ORG statement is not translated into OBJECT CODE by the assembler. For this reason, it and other assembler directives are also called "PSEUDO OP"s.

There are several other assembler directives which are used in preparing source code for the assembler's use, These include the EQUate and REServe statements. $\underline{\text{EQU}}$ directs the assembler to assign a specific

COMMENTARY: (CONTINUED)

numeric (hex code) value to a symbolic label. Once defined, the label will be translated by the assembler to its hex code equivalent each time it is encountered in the source code. RES directs the assembler to REServe 1 or more memory locations for some specific function defined in the LABEL field.

When writing programs for the assembler, it is very useful to insert COMMENTS before or after various blocks of source code. The asterisk symbol (*) is used to define a line of source code as a comment. Upon detecting an asterisk, the assembler makes no attempt to translate succeeding source code on the same line into object code.

In operation, the assembler sequentially scans the mnemonic code you have written for each instruction. It generates the hex-code for each instruction, storing these codes in its memory. In some cases, such as in translating BRANCH instructions, the complete hexadecimal code for the instruction may be unknown. For example, assume that a $\underline{\text{BCTA}}$ (Branch on Condition True - Absolute addressed) instruction is encountered in line $\underline{40}$ of a listing. Further, that the branch location (in memory) is not defined until the assembler encounters line $\underline{65}$. During the $\underline{\text{FIRST PASS}}$, the assembler will "save" enough memory for eventual storage of the destination address, in this case, 2 bytes. Eventually, the address label, in line $\underline{65}$, is defined; the assembler saves this information in a $\underline{\text{data table}}$ of its own. Then, during a $\underline{\text{SECOND PASS}}$, the assembler scans this table for missing addresses, inserting them into the saved memory locations as required. After the assembler's second pass is complete, it will generate, on command, a PRINTOUT of the entire listing, including all $\underline{\text{directives}}$, source code, object code, and its own $\underline{\text{label tables}}$.

NOTES:

THIS PAGE IS LEFT BLANK INTENTIONALLY.

The following chart specifies designated file number(s), and a short description of each program digitally recorded on the INTRODUCTORY CASSETTE tape. Details and variations of each program are provided later in this chapter. The first page of each program's documentation is identified immediately below its name in the table below.

PROGRAM	FILE	DESCRIPTION
B I L L B O A R D -21-	1	BILLBOARD provides a capability of viewing any user-defined message in the Hex display. Message length is programmable to a maximum of 254 characters. The entire message moves from right to left across the display, and repeats automatically.
D E S K C L O C K -24-	2	Using your local AC line frequency as a time source, DESKCLOCK transforms the INSTRUCTOR 50 into a 4-function desk clock. The program permits the user to preset hours, minutes, seconds, and a unique AM/PM indication, then to start the clock, all from the keyboards.
S T O P W A T C H -34-	3	Accurate to within 1/10th of a second, STOP-WATCH extends the INSTRUCTOR 50's capability to act as an event or elapsed time counter. Fully programmable, STOPWATCH permits its user to "freeze" (and display as well) up to 4 separate times while it is running, all without any alteration of its accuracy.
C R A P G A M E -45-	4 4 A	Programmed to conform to a modified set of Nevada Casino Pass Line rules, CRAPGAME may be played by the single user or by several players as well. Following the user's "buy into the game" and "bet", the "dice are rolled". After the roll, the program determines whether the player has won, lost, or must roll again. Winnings (and losses) are added to (subtracted from) the player's current chips automatically.
BEAT THE ODDS VERSION 2 -62-	5	BEAT THE ODDS is a numbers game in which one or more players bet against the odds of a specific hex-digit pair or binary pattern being generated by the INSTRUCTOR 50. A convenient ODDS TABLE diagram is provided in the documentation associated with this program.
SLOTMACHINE -68-	6 6 A	SLOTMACHINE features 3 independently rotated "image wheels". After the wheels stop, the program tells the player whether he lost, or if he won. For winning combinations, the IN-STRUCTOR 50 calculates and displays the odds for payoff by "the House", and goes absolutely berserk when the player "hits the JACKPOT!"
T R A I N -85-	7	While executing program TRAIN, the operator may select any 1 of 16 different "train" character sequences for display in the "SWITCH-YARD. Further, he may run the selected train forwards or backwards at any 1 Of 7 speeds.
INSTRUCTOR 50 MUSIC THEME -94-	8	The music you heard on the Introductory Tape was generated by this program as executed by the INSTRUCTOR 50. You may create your own tunes, simply by modifying the pitch and duration data tables associated with INSTRUCTOR 50 MUSIC THEME.

MEMORY DISPLAY & ALTER MODE

INTRODUCTION:

There will be many times when you'll want to alter or display the contents of specific memory locations. In running the programs supplied in this chapter, you'll have occasion to change the display time of various messages. In other words, you'll want to "tailor" each program to your acceptance level. When you write your own routines and programs, you'll also debug them by changing the value of a byte, altering memory as required by your application's software. You'll use MEMORY DISPLAY & ALTER mode to accomplish these changes, in addition to other deletions, additions, and substitutions your program requires. You'll also employ this mode to VERIFY the contents of memory you may load in FAST PATCH mode.

PROCEDURE:

- Depress MON, MEM, and to define the specific address of the 1. 1 to 4 HEX keys. byte of interest. The selected address is displayed, and may be changed until you depress ENT/NXT.
- 2. Depress ENT/NXTto set the desired address. The INSTRUC-TOR 50 responds by displaying the current data contained in the selected memory address.

* *****************

- 3A. the next memory location, with NO DATA CHANGE to the current address's contents. USE THIS OPTION TO VERIFY MEMORY CON-TENTS WITHOUT CHANGE.
- 3B. Depress 1 HEX key andto change the selected byte's least sig-ENT/NXT. nificant digit (bits 3-0). The most significant digit is ZEROED.
- Depress 2 HEX keys and to alter the entire contents of the se-3C. lected memory location. Current data is ENT/NXT. SET and the address is INCREMENTED when you depress ENT/NXT.

MEMORY DISPLAY & ALTER MODE CONTINUED

EXAMPLE:

In routine "DISMES" (below), the <u>display time</u> of messages included in program "CRAPGAME" is controlled by data contained in location $H'\not\!\! D13D'$ of memory. The value may be varied between $H'\not\!\! D1'$ and $H'\not\!\! DA'$, to provide message display times equal to 0.25 and 2.5 seconds respectively (in 0.25 second increments).

Modify the contents of location H'013D' as you wish in order to provide a desired message display time:

		ROUTINE	E DISM	MES	-	STA	RT ADDR 13	PART	OF PROGRAM CRAPGAME	2 6
		DESCRIP	PTION						D DISPLAY TIME OF NS '1780' TO'17BE	
		LINE	ADDRS		DATA B1		LABEL	SYMBOI OPCODE	IC INSTRUCTION OPERANDS	
Ø 1 3 C	0.5 (0.2)	4								ON ENTRY
DIJC	0 3 (0 2)	5	Ø13A	CA	7B		DISMES	STRR,R2	>MESLOC-1	INDEX TO
		6	C	05	(02)			LODI,R1	2	NOW SET
		7	13E	C9	79		REPEATM	STRR,R1	RUNDSPX	OUT & ST
		8	140	CB	76		DSPAGN		DSPLDLY	STATIC/D

- 3. Depress $\underline{\text{MEM}}$, $\underline{1}$, $\underline{3}$, $\underline{\text{D}}$, to select, then set the address of the and $\underline{\text{ENT/NXT}}$. desired byte. The message:

"013d. 02" is displayed.

- 4. Depress $\frac{1}{4}$, and to DOUBLE the display time of "CRAP-ENT/NXT. GAME"'s messages.
- 5. Repeat steps 1 through.....keying in different values for location 4.

 H'013D', until the value which represents your desired display time is stored in memory.

NOTE:

YOU'LL BE ABLE TO PERFORM THE ABOVE PROCEDURE AFTER YOU HAVE LOADED PROGRAM 'CRAPGAME' INTO THE INSTRUCTOR 50'S MEMORY, EITHER FROM TAPE OR IN FAST PATCH MODE.

NOTES:

MEMORY FAST PATCH OPERATIONS

INTRODUCTION:

Within the listings contained in this chapter, there are many variations to each application, which may be accomplished by changing the contents of a BLOCK of CONTROL PROGRAM memory. You'll use MEMORY FAST PATCH, one of several INSTRUCTOR 50 operational modes, to load and modify these blocks of memory. FAST PATCH is also employed in restoring smaller blocks of memory, such as 8-byte messages, to their original data values. This is illustrated in the example on the opposite page.

PROCEDURE:

- 1. Depress MON, REG, and "F" To enter MEMORY FAST PATCH mode. The message:

 ".Ad. = " is displayed.
- 2. Depress 1, 2, 3, or 4 HEX To select the address of the 1st byte keys

 you'll be loading into this memory block.
- 4. Depress TWO Hex keys for..... Start with the data contained in the each byte of data to be selected start address. As each memory location is loaded, the displayed address will be INCREMENTED by 1. Repeat Step 4 until the entire block of specified memory is loaded.

NOTE:

WHILE YOU ARE KEYING DATA IN FAST PATCH MODE, NO DATA CHANGE IS POSSIBLE. IF YOU KEY AN UNDESIRED VALUE, EXECUTE ONE OF THE FOLLOWING KEY SEQUENCES, DEPENDING ON THE CURRENT HEX DISPLAY READOUT.

- (1) Depress REG, 'F', ENT/NXTif the <u>address</u> of the data error is still displayed. The INSTRUCTOR 50 will display the message:

 ".XXXX " where 'XXXX' is the address of the byte requiring change
- (2) Depress REG, $\underline{'F'}$, thenfor the desired address of the byte- $\underline{1}$ to $\underline{4}$ HEX keys, then $\underline{-in}$ -error, if the desired address is no longer displayed.

MEMORY FAST PATCH OPERATIONS CONTINUED

Then, key in the desired data as defined in step 4.

EXAMPLE:

CHANGE DATA AS SHOWN IN THE LISTING (BELOW)...TO THESE VALUES:

- 1. Depress REG, F, 3, 8, ENT/NXT.....Start address is H'0038'.
- 2. Depress HEX keys:

NOTES:

WRITE CASSETTE OPERATIONS

INTRODUCTION:

As you become more and more proficient in the art of writing programs for the INSTRUCTOR 50, you'll want to save them for future recall on tape. Once your program is stored on tape, you need only to perform the easy READ CASSETTE operational procedure to reload the INSTRUCTOR 50's memory. It is particularly useful to store "programs in process" as a means of recalling their historical content during debug. Many programmers also store specific routines or program segments. If a subsequent application requires use of one or more of these segments, each is easily recalled, then located as desired in the new application's program. Much time is saved, since you need not manually key in the desired routine.

Your <u>selection</u> of recording tape is very important. All tape has imperfections in its magnetic surfaces. For the music buff, this makes little difference; he'll probably never detect the intermittant blemish. The INSTRUCTOR 50, like all other digital data machines, will detect imperfect recording as a LOSS OF ONE OR MORE BITS OF DATA. This results in an ERROR display on the INSTRUCTOR 50. To minimize data loss problems, use good quality low-noise tape. Also, record a <u>safety copy</u> of each of your programs. When purchasing blank tape cassettes, select those which are biased for your recorder's operation. We recommend use of short-time tapes (e.g.: C-30, or C-45 cassettes) in order to minimize "hunt time" during your file searches. <u>NOTE:</u> SHORT-TIME TAPES ARE MANUFACTURED WITH A THICKER BASE, THUS, THEY ARE <u>STRONGER</u> AND LESS SUBJECT TO MAGNETIC "PRINT-THROUGH". Before recording an actual file on tape, we recommend that you vocalize a brief introduction to it. The introduction should include:

- * the desired File number
- * the name of the program or routine
- * lower and upper memory addresses of the memory block to be stored as a file.
- * the start address for program execution, <u>espe</u>-cially if it is not address '0000'.

The introduction will probably require no more than 20 seconds of tape, and serves as a convenient "leader" between recorded segments of digital data. It is useful as well to keep a written record of the files stored on tape. In addition to the information contained in the verbal file leader, you may wish to include a few notes regarding INSTRUCTOR 50 control switch settings or other operator activities. If your recorder is equipped with a TAPE COUNTER, identify the approximate count (from 000) where each file is contained on tape. You'll simplify your file search operations later.

Finally, insure that your recorder's tapeheads and mechanical components are CLEAN, lubricated, and operate smoothly. The operations booklet for your recorder tells exactly what's necessary.

WRITE CASSETTE OPERATIONS

HOCL	DURE: ACTIVITY	COMMENTARY
1.	Install the cassette in your recorder, and vocalize the introduction to the next file.	Page 6-10 provides a short list of items you may wish to include in your introduction.
2.	Connect the audio cable between the INSTRUCTOR 50's $\underline{\text{MIC}}$ jack & the $\underline{\text{MIC}}$ rophone input to your recorder.	Do not use your recorder's "AUX" or "LINE" input unless your recorder's MIC input overloads or distorts.
3.	Depress MON and WCAS	.To enter "WRITE CASSETTE mode. The message: "LAd = " is dis- played.
4.	Depress 1, 2, 3, or 4 HEX keys to define the LOWER address of the memory block to be stored on tape.	Display: " $\underline{LAd} = \underline{XXXX}$ " where 'x' is the value of each hex key.
5.	Depress ENT/NXT	to set the lower address. The message: "UAd = "is displayed."
6.	Depress 1, 2, 3, or 4 HEX keys	to define the UPPER address of the memory block to be stored. The message: "UAD = XXXX" is displayed where 'x' is the value of each hex key.
7.	Depress ENT/NXT	to set the upper address. The message: "SAd = " is displayed.
8.	Depress 1, 2, 3, Or 4 HEX keys	to define the program execution start address of the memory block represented by this file. Display: "SAd = XXXX".
9.	Depress ENT/NXT	to set the start address. The message: " $\underline{F} = \underline{\hspace{1cm}}$ " is displayed.
0.	Depress 1 or 2 HEX keys	to define the <u>file number</u> of the memory block to be stored. Display: " $F = XX$ ". ' $xx' = file$ number.

WRITE CASSETTE OPERATIONS

PROCEDURE: (CONTINUED)

- 11. Depress ENT/NXT and immedi-..... You have about 6 seconds to do this, ately place your recorder in RECORD mode.

 after which your program's digital data transfer to tape is initiated. The Extended I/O LEDs flash for the duration of the transfer.
- 12. STOP your recorder...... when the message "HELLO" is displayed. "HELLO" indicates that the data transfer is completed.

If an additional file is to be stored on tape, repeat step 1, and steps 3 through 12. At your option, record a "SAFETY COPY" of each file stored on tape. In your verbal introduction, mention the file number, and the fact that this is a safety copy.

NOTES:

TAPE RECORDER LEVEL ADJUST

INTRODUCTION:

The following procedure is provided as a practical means of calibrating your tape recorder's output $\frac{1 \text{ evel}}{1 \text{ evel}}$ (volume) and $\frac{1 \text{ tone}}{1 \text{ tone}}$ controls for loading digital data from tape to the INSTRUCTOR 50. By following this practical procedure, you'll achieve a very high rate of success in subsequent program recall.

- 1. Ensure that your recorder's tapeheads, capstan, pinch roller, and other mechanical assemblies are clean and operate smoothly. Your recorder's Operations Booklet will inform you of the proper sequence you must follow.
- 2. Use your recorder's FAST FORWARD or REVERSE controls to position the desired source program file <u>over</u> the playback head. You can do this with the volume control reduced for comfortable listening level.
- Connect an audio cable between the INSTRUCTOR 50's PHONE jack, and your recorder's PHONE or MONITOR jack.
- 4. Set your recorder's TONE control (if present) in the high TREBLE range. Set the BASS tone control (if present) to its most attenuated value.
- 5. On the INSTRUCTOR 50, depress \underline{MON} , \underline{REG} , and $'\underline{A}'$. The Hex display will go blank.
- 6. Start your recorder in $\underline{\mathsf{PLAYBACK}}$ mode. Then adjust its output volume control for higher output. The INSTRUCTOR 50's Hex display:
 - * will be blank
 * will display a 'U'
 * will display a '-' (dash)
 * will display a 'd'
 IN SEQUENCE AS YOU
 INCREASE VOLUME
- 7. As soon as the 'd' is displayed, <u>DECREASE</u> volume until the '-' (dash) reappears in the display. Do <u>not</u> adjust the volume control further.
- 8. Alternately REWIND the tape for a few turns, and PLAY-BACK for a few seconds. During playback, the "dash" will reappear in the display until you have rewound the tape to the start of the desired program's data.

 Ignore display indications during the short rewind operations. When the "dash" no longer appears in the display, stop the recorder, and go right on to perform the READ CASSETTE procedure.
 - NOTE: PERFORMANCE OF STEP 8 ELIMINATES ANY
 NEED TO LISTEN FOR THE START OF DIGITAL
 DATA ONCE THE LEVEL IS ADJUSTED. IN ITS
 OWN WAY THE INSTRUCTOR 50 DOES THIS FOR
 YOU.

READ CASSETTE OPERATIONS

INTRODUCTION:

You'll use this procedure over and over again as you play back digital programs from the Introductory cassette, or from your own program "library" into the INSTRUCTOR 50.

NOTE: NO MAGNETIC RECORDING TAPE IS MANUFACTURED PERFECTLY. DESPITE STRINGENT PROCESSES, THE TAPE'S ABILITY TO STORE DATA EVENLY MAY VARY BECAUSE OF THE TAPE'S OWN MAGNETIC STRENGTH CHARACTERISTICS. FOR THIS REASON, YOU'LL FIND THAT IT IS YOUR ADVANTAGE TO PERFORM THE TAPE RECORDER LEVEL ADJUST SEQUENCE EACH TIME BEFORE SEQUENCING ANY READ CASSETTE OPERATION.

PROCEDURE:

VERIFY THE FOLLOWING:

- (a) The audio cable is connected between your recorder's PHONE or MONITOR jack, and the INSTRUCTOR 50's PHONE input jack.
- (b) Your recorder's VOLUME (Output Level) and TONE controls are properly calibrated.
- (c) Your recorder's PLAYBACK head is properly positioned over the <u>start</u> of the desired file's digital data.

2. DEPRESS THE FOLLOWING KEYS ON THE INSTRUCTOR 50:

MON, RCAS,

1 or 2 Hex keys,

ENT/NXT.

to identify the desired file you wish to load from tape into the INSTRUCTOR 50's memory.

ENT/NXT initiates the file search.

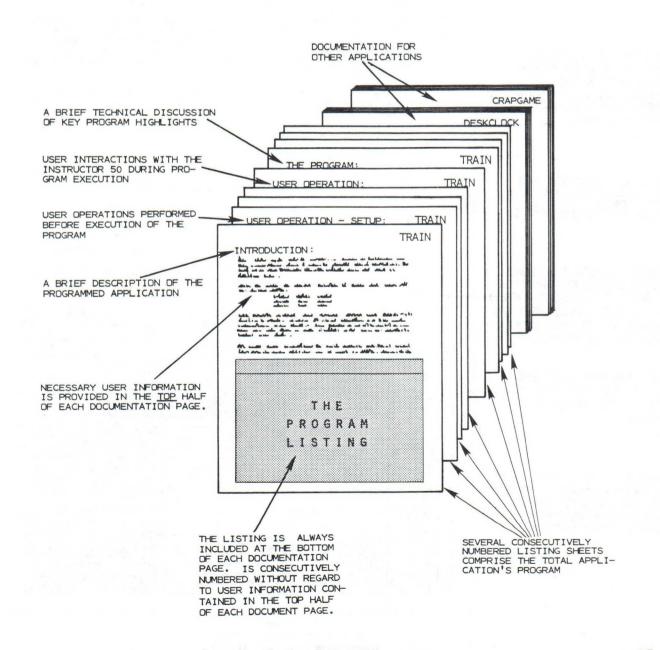

> NOTE: THE I/O MODE SELECTION SWITCH MUST BE IN THE 'EXTENDED I/O PORT 07' POSITION FOR YOU TO VIEW THE I/O LEDS.

4. STOP YOUR RECORDER WHEN THE INSTRUCTOR 50 DISPLAYS: "HELLO".

When the INSTRUCTOR 50 displays the message: "HELLO", the memory load from tape is complete. Stop (and store your recorder, and execute the desired program. If the program is contained in 2 files, repeat steps 1 through 4 (above). Do NOT change the volume or tone control settings on your recorder.

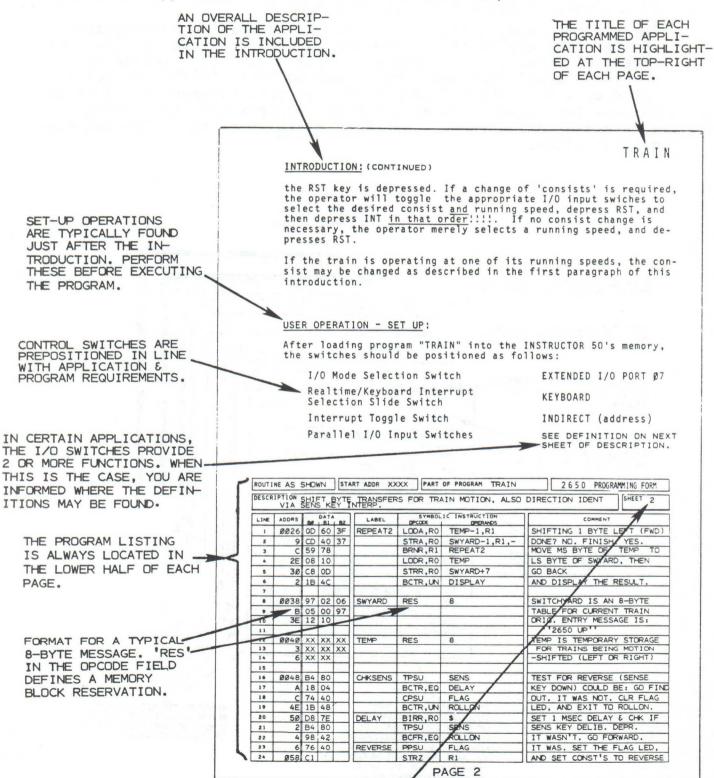

Documentation which defines any microprocessor-controlled application is every bit as important as the software and hardware which together provide realization of the application. At first glance, good technical documentation can be rather intimidating in its complexity, especially to the novice.

There are as many different formats for preparing documentation as there are application engineers and software specialists. Two essential formats are illustrated. The first, illustrated by programs "BILLBOARD" and "INSTRUCTOR 50 MUSIC THEME", is generated by a SOFTWARE DEVELOPMENT SYSTEM manufactured by Signetics Corporation. Typically, this method supports its application with a few terse comments and flowcharts which summarize the program sequence.

HOW TO USE THIS DOCUMENTATION (CONTINUED)

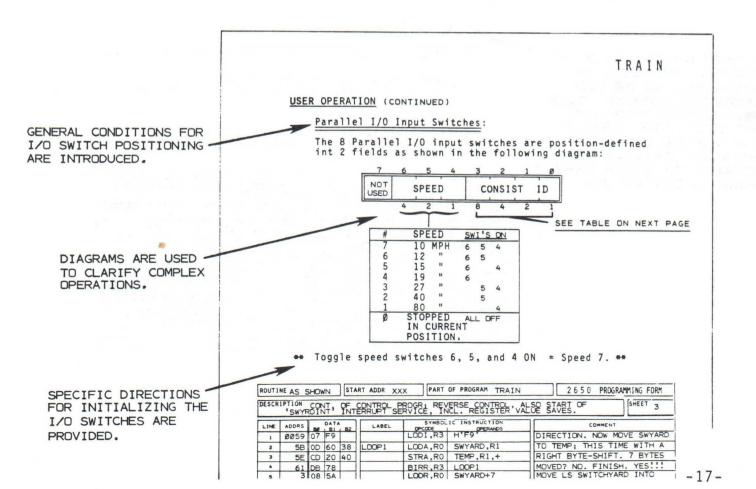

The second method, although more complex, is particularly useful when you are preparing the software and user-interactive parts of an application without the assistance of an ASSEMBLER or other software development system. To reduce its complexity, this format is diagrammed in these 6 pages. Practical use and flexibility of the format are then provided in the descriptions of the TIME and GAMES applications found later in this chapter.

THE SHEET NUMBER COR-RESPONDS TO THE APPLI-CATION'S DOCUMENTATION

PROGRAMMING NOTE

On some of the listing pages for the various programs, you'll find that NOT all sequential memory locations are programmed. If you use the INSTRUCTOR 50's FAST PATCH or MEMORY DIS-PLAY & ALTER modes to load user storage from the listing, PROGRAM "FILLER CODES"; H'ØØ', in undefined addresses.

USER SET-UP PROCEDURES ARE FOLLOWED BY PRECISE DEFINITION OF USER ACTI-VITY WHEN THE PROGRAM IS EXECUTED.

TRAIN

USER OPERATION: (CONTINUED)

5. Depress RST

If the train consist is stopped.

NOTE: TURN ON AT LEAST <u>ONE</u> OF THE SPEED CONTROL SWITCHES PRIOR TO DEPRESSING THE RST KEY.

6. Toggle input switches $3, 2, 1, \text{ or } \emptyset$

To select any other consist. Try them all, at different speeds.

7. Depress INT

to move the selected consist into the switchyard.

THE PROGRAM:

There are 2 major points of interest in program "TRAIN"; these include:

* Forward and Reverse Motion Control, and

Selection & Transfer of the desired Consist into the Switchyard.

FORWARD AND REVERSE MOTION:

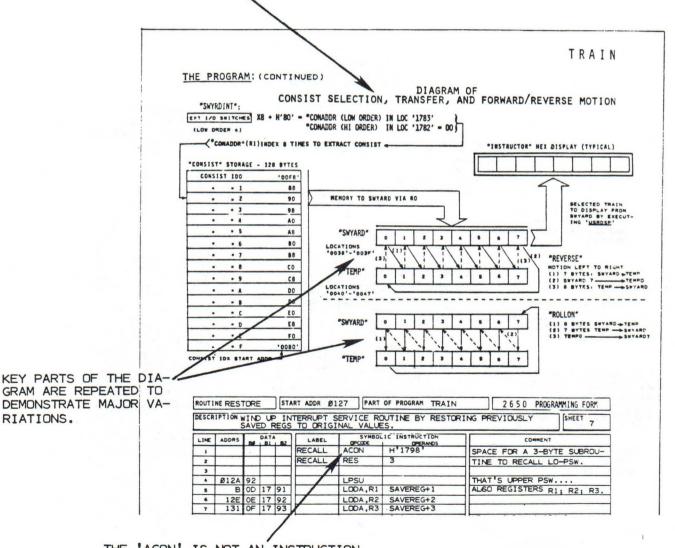

Refer to the diagram on the next page, also to the highlights pointed out in the $\underline{\text{Listing}}$. The description is provided on sheet 8.

ROUTI	NE CON	TIN	T	STA	RT ADDR Ø12	PART	OF PROGRAM TRAIN	2 6 5 0 PROGRAMMING FORM

POINT IN SOFTWARE USE.

RIATIONS.

PROGRAM HIGHLIGHTS OF COMPLEX NATURE ARE SUPPORTED BY DIA-GRAMS AND OTHER USEFUL TABLES TO MAKE THE LEARNING PROCESS EASIER. YOU ARE URGED TO USE THESE DIAGRAMS WHILE TRACING THE FLOW OF THE PROGRAM IN THE LISTING. BY DOING THIS, YOU'LL 'SEE' PROGRAM EXECU-TION AS THE COMPUTER DOES!!

THE 'ACON' IS NOT AN INSTRUCTION OPCODE. IT IS WRITTEN BY THE USER TO DEFINE AN 'ADDRESS CONSTANT' IN MEMORY. IN THE EXAMPLE, 'RECALL' IS LOCATED IN MEMORY AT ADDRESS '1798'. THE 'RES' STATEMENT IM-DIATELY FOLLOWING INDICATES THAT 3 BYTES ARE RESERVED FOR ROUTINE RECALL !

PROGRAMMABLE BILLBOARD

INTRODUCTION:

The first of a variety of programs provided on the INTRODUCTORY CASSETTE tape, "BILLBOARD" provides a means for you to prepare, then display your own messages on the INSTRUCTOR 50. The maximum message length is 254 separate characters, including space codes (Blanks), and other graphics. In it's taped version, the message: "HI, THIS IS THE 2650." is displayed. All messages move from right to left across the display window.

The following table provides the code for each character of the display "font". Use it to prepare your messages. In addition, you may experiment with any <u>unlisted</u> codes in order that you may generate "special graphics". In program "TRAIN" (located elsewhere in this chapter), <u>special graphics</u> are used to define the <u>rolling stock</u> of each train.

CHARACTER FONT:

SYMBOL	CODE	SYMBOL	CODE	SYMBOL	CODE
0,0	00	В	OB	0	15
1,I	01	C	OC	=	16
2, Z	02	D	OD	blank	17
3	03	Ε	OE	J	18
4	04	F	OF	- (DASH DE MINU	us) 19
5,5	05	P	10	*	1 A
6,G	06	L	11	Υ	1 B
7,T	07	U	12	(SMALL BOX)	95
8	08	R	13	N	1 C
9	09	Н	14	T	6 C
Α	0 A				1

NOTE: Add H'80' to the character code if you desire a RIGHT-JUSTI-FIED DECIMAL POINT. Terminate each message with the code: H'FF'.

USER OPERATION:

Depress $\underline{\mathsf{RST}}$ to start "BILLBOARD". None of the INSTRUCTOR 50 control switches are used; no special positioning is required.

THE PROGRAM:

The listing for program "BILLBOARD" is provided on the next 2 pages. The first sheet of listing is given over to a brief description of the program, followed by definition of various symbols in terms of their HEX CODE equivalents. <u>EQUate</u> statements are input to the AS-<u>SEMBLER</u> to perform this function. Before any symbol can be used by an assembler, it must be defined.

On the following sheet of listing, \underline{ORG} (Program \underline{ORiG} in) statements define both "BILLBOARD"'s <u>start</u> address, and the <u>location</u> of the MESSAGE's first byte. You may insert the message of your choice, starting at location H'101'. In line $\underline{78}$, a memory <u>RES</u>erve statement dedicates a single byte, at address H'100', for use as a 'message pointer. The current 8 byte message is displayed, then the pointer is incremented. The 8 code bytes immediately following the memory location defined by the pointer are displayed, with the pointer being used as the LEAST SIGNIFICANT byte of address.

4 - FUNCTION DESK CLOCK

INTRODUCTION:

A full 4-function desk clock is implemented via the facilities of the INSTRUCTOR 50 when program "DESCLK" is loaded and executed. These functions include HOURS, MINUTES, SECONDS, and a distinctive AM/PM indication. All four time functions are preset from the HEX KEYBOARD; there is no need to use the INSTRUCTOR 50's "Display and Alter Memory" mode once the program is loaded. Special command requests are asserted in sequence to prompt the user to enter expected time parameters.

Once the time functions are entered, the set time is displayed in <u>static</u> mode. When the operator determines that the displayed time equals the exact time-of-day, he depresses the SENS key to start the clock running.

The desk clock is equally at home in a 50 Hz. environment. The operator needs only to modify one byte of data in the control program to change the clock's activity from 60 to 50 Hz. Minor modification of the program also permits usage of the desk clock as an interval timer, capable of displaying accurately in 1/10th second increments.

Typically, the operator will preset the desk clock a minute

INTRODUCTION: (CONTINUED)

or so fast, then call the local telephone company's <u>time check</u> service to synchronize the clock. Since this clock uses the AC line frequency as a time source, it can not lose (or gain) time unless power is lost.

The leading hours digit is blanked automatically when the time cycles from 12:59 to 1:00, remaining blanked until 10:00 o'clock. All times between 12:00 noon and 11:59::59 PM are identified by the PM indicator, a small box located between the minutes and seconds display. Absence of the small box defines AM times. Typical time displays are shown below:

User operation is defined on the next page.

USER OPERATION (CONTINUED)

THE PROGRAM:

There are 3 major functions included in program "DESCLK"; these include:

- 1. a <u>time preset sequence</u>, during which the INSTRUCTOR 50's User Display and Get Numbers subroutines are accessed in order for the user to set the clock.
- 2. a <u>REAL-TIME Interrupt</u> sequence, in which the actual high-speed incrementation of time takes place, with resulting time values stored in a special <u>clock display buffer (at address h'100')</u>.

THE PROGRAM (CONTINUED)

- 3. a series of routines designed to handle anomalies and exceptions from the strict increment method used in incrementing the time functions. These include:
 - * "HIHRS"a routine which tests upper hour changes to see if it is time to change the AM/PM indicator.
 - * "TESTHRS".....This routine checks to see if it is 10:00 yet. If so, TWO hour-digit changes are necessary.
 - * "AMPM"......Controls set or reset of the AM/PM indication at 12:00.
 - * "END"......Controls initialization of hours at 1:00 0'clock.

In the listing, sheet 1, the routine "CONT" is employed in static time mode to test for activity of the SENS input after the clock is preset. This test is determined by FLAG (not active), and branch to subroutine "CHKSENS". Once SENS is depressed, the FLAG bit is set. Thereafter, routine "CONT alternately displays the 'Time of day', and tests for activity of the 60 (50) Hz AC LINE input. Until SENS is depressed, all interrupts are inhibited, and the real-time interrupt is not tested. Tight control of interrupt recognition is maintained by opening an 'interrupt window' only during a precise time in the sequence.

THE PROGRAM (CONTINUED)

In sheet 2, a modulo 60 (50) counter is established by the ADD and COMI instructions (LINES 8 ϵ 9). The frequency counter (FREQCT) is reinitialized to zero in routine "INCSEC" (LINES 15 AND 16)

Modulo 10 and modulo 6 counters are employed in the processes "INCSEC", and "INCMIN", thus providing for orderly incrementation of seconds and minutes from \emptyset to 60. These routines are streamlined by handling their calculations in hex, thus eliminating a requirement for repetitive 'Decimal Adjust' instruction usage. Hours increment from 1:00 to 10:00 is also handled the same way.

AM/PM Indication is handled simply by swapping the codes for the PM Indicator 'box' and 'space' each time the clock has incremented to 12:00 (SHEET 5; LINES 1 THROUGH 8).

Clock preset is initiated by setting the AM/PM indicator code in subroutine "AORPM" (SHEET 6). Here, the HEX KEY code depressed by the operator in response to the "A OR P =" prompt, is compared with H' \emptyset A'. If the compare is valid, it's AM, so a spacecode is inserted into the PM Indicator location in the clock display message. If there is no valid compare, the PM indicator code (H'95') is inserted into the same location.

THE PROGRAM (CONTINUED)

Routine "SETIME" is the control program required for hours, minutes, and seconds preset sequence (SHEET 8). An EVENT COUNTER (R1) is setup in line 6. Count is 3, there being 3 major sequences for data entry (\underline{hours} , $\underline{minutes}$, and $\underline{seconds}$. Indexed message control (in 8-byte increments) is maintained to provide display prompts to the operator for time entry.

Actual time value entry is handled by routine "NOWSET" (SHEET 7). "NOWSET" calls Monitor subroutine "GNPA" in order to permit the operator to enter the time from the HEX KEYBOARD after the appropriate prompt message is placed in the Display Buffer of the Monitor. After the numbers are selected by the operator, they are split into contiguous nibbles. The most significant nibble is checked for a zero value, in which case subroutine "BLNKZ" insets a space code into the M.S. HOURS position of the clock display message.

Routine "ORDER" controls the display time ($1\frac{1}{2}$ seconds) of the message "SET CLOC", viewed once when the operator depresses the RST key. "ORDER" is located in sheet 9 of the listing. A block of four 8-byte messages is found in sheet 10.

This concludes the explanation of program "DESCLK".

PROGRAMMABLE STOPWATCH

INTRODUCTION:

DOUTINE AC CHOWN START ADDR GGGG

The INSTRUCTOR 50's REAL TIME interrupt facilities are featured in the program for an extremely accurate STOPWATCH application. This is no ordinary stopwatch, however; you have the capability to "freeze" up to $\underline{4}$ different \underline{times} while "STOPWATCH" is running, all without affecting its accuracy. In addition, you may "review" each frozen time, simply by depressing the appropriate hex key. Again, the internal clock 'mechanism' keeps running at designed accuracy.

Practical use of this "STOPWATCH" can take a myriad of forms. Think of its application at track and swim meets, where precise lap times must be determined by the coaches and participants, both to improve their performance, and in formal competition. The "STOPWATCH"'s 1/10th second digital readout will literally stop arguments over true time in all but the fastest races. At the horse or dog races, you may have the need to freeze times at the quarter mile, half pole, and at the head of the stretch. As an aid to your timing televised events, such as the Kentucky Derby, or the Olympics, its unbeatable!

In its original form, "STOPWATCH"'s "running clock" times from zero to 1:59::59.9 in tenth of a second increments. For easy readability, an "odd hour" indicator is blanked until timeout of the first hour (0:59::59.9) is completed. At 1:00::00.0, the

A JOHN GARCEAU PROGRAM

INTRODUCTION: (CONTINUED)

the "odd hour" indicator, a small box in the left-most display digit location, is turned on. It remains on until "STOPWATCH" cycles automatically into the next (even) hour.

Two variations (described later) provide you options to stop the "STOPWATCH". The first, programmed in the tape you've received, stops the clock when the AC Line/Keyboard Interrupt Slide switch is moved to the KEYBOARD position. The second option stops the watch if any key in the second column (from the right) in the Hex Keyboard, is depressed.

NOTES:

Set up and operating procedures start on the next page.

USER OPERATION - SET UP:

After loading program "STOPWATCH" into the INSTRUCTOR 50's memory from tape, position the control switches as follows:

AC Line / Keyboard Interrupt Selection Slide Switch:

AC LINE

Interrupt Address Select Sw:

INDIRECT

I/O Selection Switch:

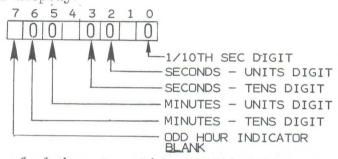

EXTENDED I/O PORT Ø7

Parallel I/O input switches:

not used

REAL TIME USER OPERATION:

Depress RST to initialize the STOPWATCH. The IN-STRUCTOR 50 responds immediately with the display:

The clock is not running. FLAG is off.

REAL TIME USER OPERATION: (CONTINUED)

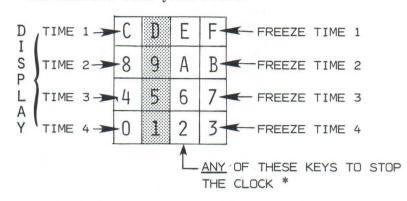

Depress <u>SENS</u> to start the STOPWATCH's run cycle.

The FLAG LED is turned on, and the

Hex Display continuously updates the current time from start.

Using the handy chart at the right, depress appropriate HEX keys:

- to FREEZE desired times
- to display previously frozen times.
- to <u>stop</u> the clock*

* If this programmable option is chosen!!!!!

TO STOP THE CLOCK IN PLACE, WITH CAPABILITY TO READ "FROZEN" STATIC TIMES:

Slide the AC Line/Keyboard Interrupt Switch to the KEYBOARD position. THIS DIRECTION IS VALID FOR THE TAPED VERSION OF "STOPWATCH".

THE PROGRAM:

In addition to the comments, provided in the listing, the following considerations are of interest:

"INITIAL" (REFER TO THE LISTING - SHEET 4)

The problem was to provide a data format of 8 bytes for each of 5 messages. This format involves zeroing bytes 6,5,3,2, & 0, and inserting space codes into bytes 7,4, and 1 of each message, prior to the time SENS is depressed to start the clock. The 40-byte memory block is first cleared, then routine "INSERT" provides an efficient mechanism to introduce space codes at desired locations. The key is provided in implementing the short subroutine "SPCD1" ((insert) one space code, then add 3 to the insertion index). This is executed 3 times. The resultant index is 1 higher than it should be after the 3rd "SPCD1" execution. To justify it to the next 8-byte message, the SUBtract instruction (LINE 17) is implemented.

 $\underline{R3}$, initialized to ' $\underline{05}$ ' in line 12, keeps track of the number of messages to be initialized.

"CLOCK" (REFER TO SHEETS 5, 6, AND 8 IN THE LISTING)

The choice of a precise location for the <u>start address</u> of this routine (at location $\emptyset\emptyset$ B8) was <u>deliberate</u>. On

Sheet 5; line 13, the $\underline{\mathsf{LODR}}$ instruction uses a $\underline{\mathsf{maximum}}$ relative $\underline{\mathsf{displacement}}$ to access FRACSEC, the 1/10th second location in the running clock message. This displacement is $\underline{\mathsf{positive}}$ with a magnitude of 63 (H'3F) bytes.

The running clock message "RUNCLK (at locations H'100' to '107') is bracketed by routine "CLOCK. On sheet 8 at line 14, the final store in RUNCLK message is accomplished by the <u>STRR</u> instruction. Here, a maximum <u>NEGATIVE</u> relative displacement (-64 bytes (H'40')) is programmed. By using relative-addressed instructions rather than absolute-addressing, <u>considerable</u> memory was saved. You can make a comparison of program lengths required to perform the SAME TASK, by inspection of program "DESKCLOCK"'s "CLK" routine. You'll see that this routine uses about 50 more bytes of storage.

"RUNCLKD"
"STACLKD" (REFER TO SHEETS 8 & 9)

At first glance, it does not appear to be useful to have 2 display routines; one for running clock, and 1 for static clock display. Both are "single pass" display routines, followed by RETC instructions. However, inspection shows that the LEAST SIGNIFICANT ADDRESS CONSTANT loaded into R2 is prepared differently in each routine. In "RUNCLKD" the constant is always H'FF'; this is why the LODImmediate instruction is used. IN "STACLKD", the Least sig. address constant, defining one of 4 possible time messages to be displayed,

is a <u>VARIABLE</u>. This variable, "CLK1234", is prepared by subroutine "SETINDX" just before "STACLKD" is executed. The LODRelative instruction (SHEET 9. LINE 3) fetches "CLK1234" into the display routine.

"SETINDX" (REFER TO SHEETS 3 & 4)

This subroutine is executed if the mainline program determines that the operator has depressed some Hex key to "freeze" or display a static time. The pattern read in from EXTENDED I/O PORT FE (KEY SENSE) is checked for binary patterns as shown at the right. If the desired pattern matches, an INDEX to the corresponding message is loaded into R1. Upon return from "SETINDX". R1's contents are :

stored in "CLK1234" if this is a retrieve operation, or

used as an index to provide a destination address for each of 8-bytes current clock in the desired "freeze" clock message.

Referring once again to subroutine "CLOCK" (sheets 5,6, & 8), there are several symbolic terms related to access of data from, or storage of data into, "RUNCLK", the running time message. The following diagram identifies the location and meaning of each of these terms:

This concludes the discussion of the program.

CLOCK READOUT ACCURACY REFINEMENT -60 HZ

Minor modifications to program "STOPWATCH" make it possible for you to interpret a combined output of the Hex Display and I/O LEDs. This feature extends the readout accuracy of "STOPWATCH" to 1/60th (0.01667) seconds. Just program the changes to the program as shown in the listing - sheet 10; below. Operate the program as specified previously. Then, when you stop the clock, use the conversion chart - below - to interpret the result.

A $50~\mathrm{Hz}$ version of this feature is provided in the listing; sheet 11 on the next page.

ELECTRONIC CRAPGAME

INTRODUCTION:

The flexible facilities of the INSTRUCTOR 50 are dedicated this time to a highly interactive "CRAPGAME" application, one in which you and you friends will enjoy time and again.

CRAPGAME operates under a modified set of Nevada casino "Pass Line" rules. After the player 'buys into the game' and places his first 'bet', the 'dice are rolled'. The 'roll' is terminated by someone depressing the SENS key.

At this point, the INSTRUCTOR 50 determines whether this is the first dice roll (PASS 1), or a roll following the first pass. Based on this condition, messages indicate whether the player won, lost, or must roll again. The following table indicates Nevada Casino Pass Line Play:

ROLL OF DICE :	2 3	4 5 6	7	8 9 10	11 12
FIRST PASS :	CRAP OUT LOSES BET	SETS POINT ROLLS AGAIN	WINS. HOUSE PAYS	SETS POINT ROLLS AGAIN	WINS. CRAPS. HOUSE LOSES PAYS BET
SUBSEQUENT PASSES :	ROLL AGAIN NO MATCH POSSIBLE	MATCH WINS. ROLL AGAIN IF NO MATCH	LOSES PAY HOUSE	MATCH WINS ROLL AGAIN IF NO MATCH	ROLL AGAIN. NO MATCH POSSIBLE

INTRODUCTION: (CONTINUED)

If the player has won or lost on this roll, the computer calculates his winnings (or losses) by adding his current bet (or subtracting it) to the current number of chips he possesses. He purchased these "chips" when he 'bought into the game'. Due to the INSTRUCTOR 50's limited user memory and complexity of CRAPGAME play, it can only track one better's current holdings. Odds for payoff are fixed; they are EVEN, paying at a 1: 1 rate.

After the current game has resulted in a win (or loss), the players are requested to place their bets once again. If the INSTRUC-TOR 50 determines that the 'on-board player' has accrued more than 100 chips (or lost more chips than he has available), the CRAPGAME in progress is over, and the I/O LEDs turn on. A new game is started by depressing RST, and the 'on-board player must 'buy a fresh number of chips.

At the start of the game, the 'on-board player' may purchase up to 99 chips. Typically, he purchases about 50, to allow for rise and fall of his fortunes. Subsequently, the player may bet up to 9 chips on the current first pass of dice. He may not change his bet once the dice are rolled.

2 C E O DOCCDAMMING FORM

INTRODUCTION: (CONTINUED)

POUTINE OFF DELOW START ADDR

The INSTRUCTOR 50 provides a variety of indications to keep the game as fast-moving as possible. These include:

- a. telling the player whether this is the 1st pass of dice.
- b. indicating the player's "win point" if he is on 2nd and subsequent dice throws.
- c. prompting the player as to his $\underline{\text{current bet}}$ and $\underline{\text{chips to-}}$ tal after each throw of the dice.

There is nothing to prevent you (and your friends) from making side bets and raising the odds 'against the house'. CRAPGAME provides plenty of time for this.

Poker chips or <u>play-money</u> are useful for multi-player CRAP-GAMES. You can raise the excitement level by designating one player as 'The House'. The other players are then provided the opportunity to control the dice roll by depressing the SENS key. The 'House' handles all other interactive functions.

USER OPERATION - SET UP:

If you are loading the INSTRUCTOR 50's memory from tape, you must access 2 files. This is required since all available user memory (including the 64 bytes available in the SMI) are required by CRAPGAME.

Set the INSTRUCTOR 50's switches as follows:

I/O Selection Toggle Switch

EXTENDED I/O PORT Ø7

I/O Input Toggle Switches (8)

any position

Interrupt Address Toggle Switch

DIRECT

AC Line /Keyboard Interrupt Selection Slide Switch

KEYBOARD

Timed message display is controlled by the value located at address $\frac{'013D'}{location}$ in the INSTRUCTOR 50's memory. Change the contents of this location from H'02' to $\frac{H'04'}{location}$ or $\frac{'05'}{location}$. This change will $\frac{lengthen}{lengthen}$ the time each message is displayed while you are getting used to CRAPGAME's operation. Later, you can restore the contents of address '013D' for faster playing action.

USER OPERATION - SET UP: (CONTINUED)

Dice roll rate is controlled by the value contained in memory at address '01C9'. Roll rate may be slowed down by increasing the value greater than H'10'. Decrease of this location's contents speeds up the roll rate. The new value should not be greater than H'7F', nor lower than H'01'. Otherwise, the roll will halt in place, and repeat forever. The contents of this location should be adjusted to a value such that you and your friends can not see any single dice pair clearly until the SENS key is depressed (too slow); also that you can clearly "see" the action of the rolling dice. H'10' is a use-

USER OPERATION - PLAYING SEQUENCE:

ful value for roll rate display control.

The sequence for playing CRAPGAME follows on the next and succeeding pages. For initial play, set the TIMED MESSAGE DISPLAY control to H'04', as described in "User set-up operations", on the opposite page.

THE PROGRAM:

Program "CRAPGAME" is organized around a sequenced mainline set of instructions, from which are called a series of dedicated subroutines as required. In sheet 1; lines 2 through 7, an indirect address table for access of supporting subroutines is listed. Typically, the mainline program calls one, or a series of more than 1, of these subroutines as it is sequenced. The major subroutines include:

"RLDICE" "DISMES"	control roll and stopping of the dicecontrols display of all messages except the
"ASMROL"	rolling dice and chips purchase messagesassembles the total of the 2 die, once
"DCDROL"	the roll has stoppeddecodes for all win, lose, and roll again
"CHIPSET"	conditions in Pass 1 and subsequent passessequences entry of the player's "Buy into
"WINNINGS"	the game"provides steering to calculate all winnings and losses, and to adjust current chip total.

The "Place Bet" routine is contained in the mainline program under the label "NEWGAME" (sheet 1; line 12). Here, the mes-

24	1CA	CB	64		AGAIN	STRR,R3	ROLDLY	THEN, FETCH THE ADDRESS

sages: "PLACE BET" & "XX BET Y" are sequenced, "PLACE BET" under the control of subroutine "DISMES", and "XX BET Y" controlled by the INSTRUCTOR 50's MONITOR subroutine "GNPA" (Get Numbers Parameters And display). "GNPA" is accessed indirectly by the \overline{ZBSR} instruction in sheet 2; line 4. Until the operator places his bet, and subsequently depresses any other HEX or FUNCTION key, the message is displayed. This type of display is controlled by programming $\underline{'05'}$ in the $\underline{LODI,RO}$ instruction; line 3.

The <u>BSTA</u> instruction (line 8) was necessary in order to permit additional programming for a bug found during proof of the program's operation.

In line 15, a constant (PASS1X) is conditioned to track whether this is Pass 1 of the dice, or whether a subsequent roll is taking place. The win/loss decode software depends on the condition of this constant in its decision making process.

Routine "PASS1", starting at line 9; sheet 2, controls all message sequencing for operations taking place during <u>Pass 1</u> dice

roll. If subsequent rolls are required (e.g. no match; no loss or win.) the mainline program sequence continues with routine "CONROL". Any winning roll detected during Pass 1 or on a subsequent roll causes program control to execute routine "BEATP1" in sheet 4. A loss detection turns program control over to the routine "BOMBOUT", in sheet 5 of the main program.

"BEATP1" and "BOMBOUT" respectively set up message displays for 'You beat the House', and 'U pay XX', then set unique constants prior to transfer of program control to subroutine "WINNINGS".

"WINNINGS" (sheet 5) compares the unique constant with one of its own: "UPAY". If the constants match, this means that the player has lost, and process "CALCLOS" (sheet 6) is executed. Here, the current bet is subtracted from current chips, then displayed in routine "WINDUP", also found in sheet 6.

If the constants do \underline{not} match, a WIN is indicated. Program execution falls through to routine "WON", where the current bet and chips are summed. "WINDUP" is then executed.

Both "CALCLOS" and "WON" test to see if the number of chips respectively exceed 100, or are less than zero. If so, routine "GAMEOVER" (sheet 6) is executed. "GAMEOVER" zeros both current

chips and bet indications, and turns on the I/O LEDs. The LEDs remain lighted until the next dice roll takes place in a new game.

Subroutine "CHIPSET" (sheet 7) accesses the MONITOR's subroutine "GNP" (Get Numbers Parameters). This differs from subroutine "GNPA" in that the least significant 3 or 4 digits are blanked when the first hex digit is depressed by the operator. This 'makes room' for data entered by the operator. The value loaded into RO (line 8; sheet 7) determines whether 2 or 4 digits may be entered, and how many preceding display digits (least significant 3 or 4 digits are blanked. The 'O1' programmed in location 'O114' conditions the routine to:

blank the 3 least significant digits, andexpect 2 digits entry with change permitted.

This is why the "EQUALS" sign goes out when you enter the first chips digit entry !!!!! Further, you've got to depress some FUNC-TION key (e.g. <u>MEM</u>; <u>REG</u>, or <u>ENT/NXT</u>) to exit from the routine.

"DISMES" (sheet 8) provides controls for both static ('display until a key is depressed') and dynamic (automatically timed-out) message display. Your author will demonstrate how you can check out both static and dynamic (timed) display later on. The key lies in the contents of R3 prior to the time the MONITOR's User Display ("USRDSP") routine is executed. As long as R3 contains a number between '01' and '7F', "USRDSP" makes one display pass, then immediately exits. If R3 equals '00', "USRDSP" will display the current message until the operator depresses some HEX or FUNCTION key. This is the reason behind programming of the COMI R3, \emptyset instruction in line 13. If R3 = 0, the player will have just depressed a key to exit the display. The following instruction, RETC, EQ is satisfied, and program control returns to the main program. All this takes place for a static display.

The instructions in lines $\underline{15}$ through $\underline{22}$ provide control for \underline{ti} -ming a desired dynamic message. Decrement of R3, from '7F' to '01', takes about 1/2 second when combined with time required by subroutine "USRDSP". Message display time is controlled by programming location '013D'. Routine "DISMES" will run the display through a precise number of single passes. The formula is:

 $(R1) \times H'7F' = SINGLE PASSES$

WHERE (R1) = VALUE LOADED INTO R1 BY THE $\underline{\text{LODI}}$ INSTRUCTION AT LINE 6. H'7F' IS THE CONSTANT INITIALIZED IN R3 BEFORE ENTRY TO ''DISMES'', OR BY THE $\underline{\text{LODR}}$ INSTRUCTION AT LINE 21.

A value of '04' initialized in line 6 provides a running display time equal to about 2 seconds. Take a few minutes to read the comments in lines $\underline{15}$ to $\underline{22}$, then continue on the next page.

Routine "DCDROL" (sheet 9) presents some interesting problems. Basically, this routine tests the <u>ASSEMBLED ROLL of dice</u> for various number values and sets an appropriate constant (in R1) for each specific value detected. All general dice possibilities are coverd; these include:

CRAPOUT 2 or 3 in dice - will be tested in PASS 1 only.

SEVEN 7 rolled - will be tested for win(Pass1) or lose.

ELEVEN 11 rolled - will be tested for a win in PASS 1 only.

PAS112 12 rolled - will be tested for crapout in PASS 1.

MATCH rolled dice = previous PASS 1 on subseq. roll.

NO MATCH If saved dice don't match this roll; main program will roll the dice on subsequent passes.

As indicated, the actual test for WIN, LOSE, or ROLL AGAIN is performed upon return to the main program from DCDROL.

Routine "ASMROL" (sheet 10) is accessed by the main program after the player depresses the SENS key to terminate the dice roll. "ASMROL"'s sole function is to set up the variables in the message "X--X = YY". After placing the values corresponding to the face-up values of the individual dice in the "X--X" portion of the message, "ASMROL" adds up the dice, and inserts the result into the "Y" part of the message. If the total equals less than $\underline{10}$, the leading "Y" digit is blanked.

Subroutine "RLDICE" is a special high-speed routine dedicated to controlling all throws of the dice. In lines $\underline{13}$ to $\underline{18}$, an $\underline{\text{index}}$ into a 36-entry data table is set up, then used to fetch a single 1-byte entry from "DICETB" (sheet 12; lines $\underline{12}$ and following). All dice combinations are contained in this table, each die face represented by a 4-bit nibble, as shown in the following diagram.

After fetch, the binary code of the "DICETB" entry is transmitted to the I/O LEDs. The entry is then split into 2 nibbles (line 20; sheet 11) and then placed in the "ROLL X X" message and displayed. The constant loaded into R3 (line 23; sheet 11) determines the display time for each current roll. After the roll display has timed out (sheet 12; line 6) the $\underline{\text{SENS}}$ key input is tested. Roll is repeated (or terminated) depending on the result of that test.

Subroutine "GETXT" (sheet 11; line 5) is accessed by routine "RLD-ICE" whenever the 'DICETB' index must be reinitialized. The $\overline{\text{TPSL}}$ instruction (line 15) tests whether the current index has carried through 'FF' to ' $\emptyset\emptyset$ '. When it does, the CARRY bit is active, and

program control branches to "GETXT". Here, the index constant is re-initialized to H'DB', the least significant byte of the 'DICE-TB's start address. The LODA instruction (line 17) adds this index to a fixed base address (' 100') contained in its 2nd & 3rd bytes. The result provides the proper memory address into the table.

In "DICETB" (sheet 12) note that the code '34' is repeated $\underline{\text{twice}}$, at locations '01DB', and at '01FA'(line 22). The code at location '01DB' is never accessed, however, since the initial index is incremented by 1 before the 1st access is made into DICETB.

The routine "DISMES" (sheet 8) accesses an 8-entry data message table; ("MESTBL") on sheet 13. Each message entry contains 8 bytes. Message variables are identified by 'XX' or 'YY' in the codes. "MESTBL" is located in the user-available memory section of the 2656 Systems Memory Interface (SMI) chip, at addresses '1780' through '17BF'.

This concludes the description of program "CRAPGAME".

STATIC / AUTO MESSAGE DISPLAY MODE CHECKOUT:

As presently coded, the mainline program does <u>not</u> exercise the STATIC message display mode feature of subroutine "DISMES". All "DISMES"-accessed messages are displayed for a short period of time only. The following modifications are provided in order to checkout STATIC DISPLAY mode:

NOTE: THIS MODIFICATION CAN WORK TO YOUR
ADVANTAGE BY PERMITTING THE PLAYERS
TIME TO PLACE INTERMEDIATE OR SIDE
BETS AFTER THE FIRST PASS OF DICE
OR EVEN AFTER EACH DICE ROLL IF THERE
IS NO WIN OR LOSS ON THE FIRST PASS.

TO DISPLAY THE STOPPED ROLL OF DICE AND THEIR TOTAL UNTIL A PLAYER DEPRESSES A HEX OR FUNCTION KEY:

PASS 1 ONLY:

Depress MON MEM 4 D ENT/NXTto select a memory alter address of the constant programmed for timed display of the message:

" X--X = YY"

Depress Ø ENT/NXT to condition the display to show the message until any key is depressed.

STATIC / AUTO MESSAGE DISPLAY MODE CHECKOUT: (CONTINUED)

SUBSEQUENT ROLLS ONLY - NO STOP ON PASS 1 ROLL:

Depress MEM 8 6 ENT/NXTaddress of memory change.

Play as usual. Both changes may be incorporated if desired. To restore, change contents at affected addresses from $|\emptyset\emptyset|$ back to '7F', as shown in the program.

I/O DISPLAY WHEN 'ON-BOARD PLAYER EXCEEDS 100 CHIPS, OR LOSES MORE THAN HE HAS:

Play in normal fashion, except 'buy into the game' with 99 (1) chip(s), and attempt to win (lose) an appropriate bet. When the limits are exceeded, all 8 I/O LEDs light, remaining on until the next dice roll takes place.

NOTES:

BEAT THE ODDS-VARIATION 1**

INTRODUCTION AND PLAY:

START ADDR ØØØ

ROUTINE AS SHOWN

This simple game will provide more "action" in an evening than you ever dreamed of, particularly if your friends enjoy some friendly wagering. Use of poker chips or play money provides a realistic excitement to the game. After you have loaded "BEAT THE ODDS" into the INSTRUCTOR 50, play as follows:

- 1. Depress RST then INT ... When the FLAG LED turns on, your friends place their bets in the field of their choice.

 Then.....
- 2. Depress <u>SENS</u> to start the random generation of numbers.

 Then.....
- 3. Depress SENS againwhen any player calls for display of the generated number.

 Bets are paid "by the House" as indicated in the 'Tables' diagram on the next page.
- 4. Depress INTto call for placing new bets

PLAYING 'TABLE'

Use a large piece of light-colored construction paper to duplicate the "Playing Table" model illustrated below. For play, place on a convenient card table facing the players. Locate the INSTRUCTOR 50 as shown.

If the player opts to select 5 or 10 specific 2-digit numbers, he should jot them down on a small piece of paper. Then, he must place the paper, together with his bet, on the table during the "PLACE BET" cycle. Any one of his 5 (or 10) numbers wins if matched.

Note: The "Table" is drawn to an approximate 1/3 or 1/4 scale.

Preparation for play is specified on page 6-65.

BEAT THE ODDS - VARIATION 1

INTRODUCTION AND PLAY (CONTINUED)

5. Repeat steps 2, 3, & 4until the message "YOU HOPE" is displayed. At this time, the game is over.

Repeat from step 1 to start a new game.

THE PROGRAM:

Program "ODDS" consists of 2 major routines; these are "ROLLING" and "DISPLAY". "Rolling" provides for a high-speed random number generation after the <u>SENS</u> key is depressed the first time. Generated numbers are 8-bit binary codes, thus 256 possible combinations may be generated.

When the \underline{SENS} key is depressed the 2nd time, the current 8-bit binary number is displayed as a 2-digit HEXADECIMAL number in the INSTRUCTOR 50's HEX DISPLAY. Each of the displayed digits may have a value equal to the following:

 $\underline{0}$, $\underline{1}$, $\underline{2}$, $\underline{3}$, $\underline{4}$, $\underline{5}$, $\underline{6}$, $\underline{7}$, $\underline{8}$, $\underline{9}$, $\underline{A}(10)$, $\underline{B}(11)$, $\underline{C}(12)$ $\underline{D}(13)$, $\underline{E}(14)$, or $\underline{F}(15)$.

The display is blanked when the operator depresses the $\underline{\mathsf{INT}}$ key to allow further betting to take place.

THE PROGRAM (CONTINUED)

The program particulars are further defined in the <u>listing</u> provided at the bottom of these pages.

PREPARATION FOR PLAY:

Place the INSTRUCTOR 50 at the rear-center of a 4 \times 4-foot card table, facing towards the center of the table.

Place the reproduced (enlarged) version of the 'Table' in front of the INSTRUCTOR 50, facing the front of the card table. Power up the INSTRUCTOR 50.

In FAST MEMORY PATCH mode, load the code for "ODDS" into the INSTRUCTOR 50.

BEAT THE ODDS - VARIATION 2*

INTRODUCTION AND PLAY:

Variation 2 of "BEAT THE ODDS" provides for enhancement of the visual display effects associated with this game. The players are told when to place their bets on the playing 'table'. Also the actual computation of the random number is preceded by a second display: "ROLL =". This is followed immediately by the 8 I/O LEDs flashing at high speed to indicate number generation.

There are slight changes to the rules of play; these include:

- 1. Depress RST and \underline{INT} to start the game. The promt: "PLACE BET" is immediately displayed.
- 2. Depress any HEX KEY......to close placing of bets. The message "ROLL =" is displayed for 4 second, followed by random number calculation.
- 4. Depress <u>INT</u> to prompt for placing new bets.
- 5. Repeat steps 3, 4, & 5until the message "YOU HOPE" is displayed

Control switch settings are <u>unchangea</u>.

* Contained as File 5 on the INTRODUCTORY CASSETTE.

BEAT THE ODDS - VARIATION 2

PROGRAM CHANGES:

The LODI,R3 \emptyset instruction (LINE 3; SHEET 1 OF 'ODDS' VERSION 2 -- BELOW) conditions the INSTRUCTOR 50's Monitor USER DISPLAY routine to display the message "PLACE BET" until the operator depresses a HEX or FUNCTION key. For ease of play, the rules specify depression of a HEX key only.

The LODI,R3 H'7F' instruction in line $\underline{18}$ conditions the Display routine for a 1/4 second timeout, with $\overline{auto-exit}$ to 'roll' for the random number.

FIFCTRONIC SLOTMACHINE

INTRODUCTION:

Program "SLOTMACHIN" provides a fastmoving means to 'play the slots', very much as a typical slotmachine is organized for use in Nevada, and now in New Jersey. The HEX DIS-PLAY facilities are used to sequence a series of messages as follows:

> "ROTATE" "YOU HOPE" "IT IS " J A C - P O T "

This is followed by rolling of the 3 slotmachine 'wheels' at an adjustable rate of speed. The 'wheels' are displayed as follows, and stop in sequence; wheel 1 first, followed by wheel 2, then with wheel 3.

XX = VARYING IMAGES FOR EACH WHEEL'S DISPLAY DEFINED ON PAGE 6-78.

A JOHN GARCEAU PROGRAM

The display is fixed for 2 full seconds after all wheels have ceased rotation to permit the viewer to see the combination rolled. Depending on the combination rolled, the player will then see the following messages:

IF THERE IS A WINNING COMBINATION:

"PAY-OFF"a 1-second message to tell the player that he has won, and that the odds for payoff will be displayed.

" X X X - T 0 1 ".....a 2-second message to indicate the exact payoff odds calculated by the INSTRUCTOR 50.

IF THERE IS A LOSING COMBINATION:

"YOU LOST"is displayed for about one second to inform the player that he lost this time.

Then, depending on certain programmable functions (easily altered by the operator), SLOTMACHIN will wait for the operator to depress RST, or automatically display the message: "ROTATE, YOU HOPE IT IS A JAC-POT", as described previously.

23								
24								

A programmable option, found in the listing, permits the player to stop each 'wheel's' rotation by depressing the SENS key. Your author recommends this option as a means of further generating a "random number sequence" for each wheel's stopping point.

In addition, all message display times are individually adjustable; these will be precisely defined in the next section of this description.

If the winning combination is 3 bars (\square \square), the player wins the "JACKPOT". The INSTRUCTOR 50 'goes berserk' by displaying the following messages 4 times while simultaneously flashing the I/O LEDs in different patterns:

" J A C - P O T "
" P A Y - O F F "
" 2 5 0 T O 1 "

The 4-event JACKPOT sequence lasts approximatlely 14 seconds. The number of events may be increased (or decreased) by minor program change.

* * * <u>L I M I T A T I O N</u> * * *

IT IS ALMOST IMPOSSIBLE TO GENERATE A TOTALLY RAN-DOM RATE OF WHEEL ROLL, AND IMAGE SELECTION WITHIN PROGRAM ''SLOTMACHIN''. WITH THE SELECTIONS PROVIDED IN THIS PROGRAM, YOU'LL FIND THAT THE PAYOFF RATE IS ABOUT 1.7 TO 1 IN YOUR FAVOR. TO MAKE THE GAME MORE INTERESTING, AND ENSURE A MODERATE PAYOFF IN THE 'HOU-SE'S' FAVOR, YOU MAY WISH TO MODIFY YOUR PROGRAM. WE WILL DESCRIBE THIS LATER. YOUR AUTHOR HAS ALSO DETER-MINED, AFTER MANY HOURS OF OPERATION, AND BY STATIS-TICAL ANALYSIS GENERATED BY HIS INSTRUCTOR 50, THAT PAYOFFS ARE CONTROLLED IN REAL SLOT MACHINES BY HOUSE ADJUSTMENT OF THE MACHINE'S INTERNAL CAMS. THUS, A TRULY RANDOM SELECTION OF PAYOFF IMAGES APPEARS TO BE IMPOSSIBLE AT GAMING HOUSES. AND CERTAINLY. IT IS IMPOSSIBLE TO PROGRAM THE COMPUTER TO LIE DELIBERATE-LY IN THE 'HOUSE'S' FAVOR, SIMPLY BECAUSE THE COMPU-TER ITSELF IS AN EMINENTLY LOGICAL MACHINE.

THIS ANALYSIS IS BASED, HOWEVER, UPON USE OF 16-IMAGE WHEELS, WITH ALL CHARACTERS IN THE SAME SEQUENCE. TYPI-CAL CASINO MACHINES CONTAIN 20-IMAGE WHEELS, WITH LESS CHERRIES IN WHEEL 1. THIS PRACTICE SUBSTANTIALLY DECREASES THE ODDS FOR PAYOFF.

USER OPERATION - SET UP:

After loading the program (2 files if via Read Cassette mode), position the INSTRUCTOR 50's switches as follows:

I/O Mode Selection Switch

I/O input Toggle switches

Interrupt Selection switch

AC Line /Keyboard Interrupt Selection Slide Switch EXTENDED I/O PORT Ø7

any position

either position

KEYBOARD

STOP WHEEL ROTATION SELECTION OPTIONS:

Refer to sheet 3 of the listing for program "SLOTMACHIN". If you loaded "SLOTMACHIN" from cassette tape, alternative 1 of routine 'STOPWHEL' is currently in the INSTRUCTOR 50's memory at addresses H'0046' through '005A'. Alternative 1 provides AUTOMATIC ROTATION AND STOP of each of the 3 'character wheels' used by the 'slotmachine'. If you desire MORE PLAYER ACTION, use the INSTRUCTOR 50's MEMORY FAST PATCH mode* to load the alternative version of routine 'STOPWHEL' into the same addresses. Alternative 2, starting at line 14 in the listing, requires the player to depress the SENS key to stop each wheel.

ROLL DISPLAY CONTROL:

The 3-wheel roll display routine is programmed to run at high speed. The following controls are offered, and may be changed:

> '03' ... current programmed wheel rotation permits 01EA distribution of 256 image changes among the 3 wheels in 5½ seconds. Increase of H'03' adds 5 seconds to wheel rotation time. Note: These times are predicated on being in automatic wheel rotation mode, described previously.

'CO' ... first wheel stops after 64 images, 004D distributed among 3 wheels, have been exercised.

'70' ... 2nd wheel stops after 144 images, 0052 distributed among 2 wheels, have been exercised.

> NOTE: YOU MAY MODIFY THESE BYTES, PROVIDED CONTENT OF LOCATION '0052' IS LESS THAN CONTENTS OF LOCATION '004D' AUTO ROTATION ONLY!!!!!!

> > 2650

USER OPERATION - SET UP: (CONTINUED)

After all the 'wheels' have stopped, the 3 resultant "images" are displayed for 2 seconds prior to testing for winning combinations. The timeout for this display is:

006C '08'.....equals 2 seconds. Increase to lengthen time. Decrease to shorten time as previously described.

AUTO/MANUAL NEW GAME OPTION:

You have the capability to select options for start of a new 'roll' of the wheels. These are provided in <u>sheets 11 and 12</u> of the listing. The 1st alternative, included in the taped version of SLOTMACHINE, provides an automatic restart, once the payoff is displayed. The second alternative requires the player to depress the RST key to restart. The following table provides a listing of the necessary codes to accomplish these options:

ADDR	CODE	INSTRUCTION	MODE COMMENT
019E	9B 00	ZBRR SLOTMACHIN	Auto Restarts after Jackpot displ.
019E	1B 50	BCTR,UN SHOWJAK	Man'lShow Jackpot message until the player depresses the <u>RST</u> key.

USER OPERATION - SLOT MACHINE PLAY:

If you chose the $\underline{\text{AUTO}}$ mode for SLOT MACHINE operation, you need only to depress the $\underline{\text{RST}}$ key, and the INSTRUCTOR 50 will perform its programmed sequence for hours on end (if you let it). AUTO mode is the best for single player operation. Incidently, this mode provides a useful vehicle for your setup and program tailoring operations previously described.

MANUAL mode configures the program so that you, and your acquaintences, can place bets "against the house" (INSTRUCTOR 50) before the 'wheels are rolled'. In MANUAL mode, you need only depress \underline{RST} once each time you wish the wheels to spin. The INSTRUCTOR 50 completes one entire sequence, then displays the latest winning odds until you depress \underline{RST} once again. However, if a LOSING combination turns up, the sequence loops back to commence a new roll. This also may be changed as shown on the next page.

USER OPERATION - SLOT MACHINE PLAY: (CONTINUED

To stop the sequence after a <u>losing</u> combination is encountered, make the following modification:

ADDR. 'ØØB1': CHANGE '9B' TO '40' . A HALT INSTRUCTION

After collecting the \underline{losses} for 'the house', have all players place new bets, then $\underline{depress}$ RST for the next sequence.

You may also wish to select the MANUAL STOP WHEEL ROTATION option involving use of the SENS key. The modifying instructions are contained in sheet 3 of the listing, and this procedure is described on page 5.

SEQUENCE:

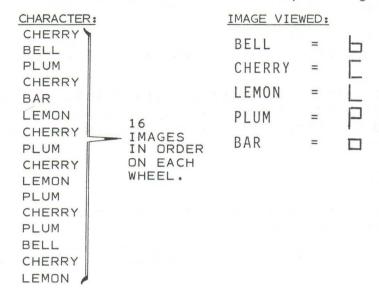

Once started, the sequence is automatic. In order, the following messages are displayed:

"ROTATE" "YOU HOPE" "IT IS A" "JAC-POT"

SEQUENCE: (CONTINUED)

The sequence is repeated automatically, or when the player depresses RST, dependant upon the mode chosen.

THE PROGRAM:

In describing the many options available to customize program "SLOTMACHIN" to your own use, much of the applications thrust of the program has also been introduced. In addition to the comments offered in the listing, the following program considerations are of special interest:

In sheets 1 and 2, a classic method for "stringing" a sequence of messages is described. Once the constants required for each message are set up, program control is turned over to subroutine "DISMES" for actual message display. Note that the TIME for each segment of the message is individually programmable.

Note the use of the $\underline{\sf BSXA}$ instruction in line 10 of sheet 2. In this case, sequential "wheel rotation" is organized as a series of $\underline{\sf 4}$ events; these are:

Event 3:....rotation of all 3 wheels.

Event 2:....rotation of wheels 2 and 3; wheel 1 stopped.

Event 1:....rotation of wheel 3; wheels 1 and 2 stopped.

Event 0:....all wheels stopped; Show the 3-image pattern.

THE PROGRAM: (CONTINUED)

During initialization (lines 14 & 15; sheet 1) the EVENTS COUNTER is set to 9 during execution of subroutine "EVENTSET" at address 'Ø13Ø'. This number is stored in R3, then used subsequently in routine "ROTATE1" as an index into a 4-entry table, "ROLL", in sheet 2. Each entry is 3 bytes long. The first time the 8SXA instruction is executed, EVENTS equals 9. Therefore, the last entry in data table "ROLL" is accessed, and program control exits to routine "ROLL123", at address Ø1ØØ. Upon return from this routine, routine "STOPWHEL" (sheet 3 --- either version) is executed, in which the stored EVENTS are recalled and decremented by 3, the length of a single entry in table "ROLL". Thus, when execution returns to routine "ROTATE1" (or ROTATE3), the 8SXA instruction accesses the next higher entry in table "ROLL, at address Ø04Ø. This time, subroutine "ROLL23" is accessed, and only the 2nd & 3rd wheels are 'rotated'. This is repeated until all 3 wheels are 'stopped'.

The use of BCTA instructions in table "ROLL" is very important. Even though these are not subroutine 'call' instructions, they all access subroutines which are terminated with a RETC instruction. This causes program control to return to the BCTR instruction following the BSXA at line 10 on sheet 2. An unconditional branch to the STOP WHEEL COUNTER routine takes place. If the count is finished, the odds will be displayed. If not, further rotation ensues.

THE PROGRAM: (CONTINUED)

As indicated previously, there are 2 <u>stop wheel</u> alternatives; these are for <u>automatic</u> and <u>manual</u> (SENS key depression) stop. Both have start addresses at location 'ØØ46', and both are listed on sheet 3.

In alternative 1 (AUTO mode), a <u>timeout</u> byte is accessed, decremented, then <u>compared</u> with each of 3 numbers; these are:

H'CO'....for stop of Wheel 1 after 64 images, distributed among 3 wheels, have been displayed.

H'70' ... for stop of Wheel 2, after an additional 80 images, distributed among wheels 2 and 3, have been displayed.

H'00' for stop of the third wheel.

If none of these numbers compare with the timeout byte's current value, wheel rotation & display continues

NOTE: YOU MAY WISH TO EXPERIMENT WITH THESE NUMBERS IN ORDER TO INCREASE OR DECREASE THE DELAY (AND SEQUENCE FOR EACH WHEEL STOP.

Upon getting a valid compare (lines 5, 7, or 9 -- sheet 3) program control exits to decrements EVENTS, as described previously.

In alternative 2 (MANUAL mode), a double test of SENS key depression takes place. This ensures that SENS is pressed deliberately. The double test is made to illustrate possible software elimination of <u>electrical noise</u> that might be present in your future application's environment. The same technique is applicable to <u>key debounce</u> procedures you may desire. The ANDI instruction (line 18) is exercised repeatedly until the operator lifts his finger from the SENS key. It is only after that, that EVENTS are decremented (by 3), and a new entry in data table ROLL (sheet 2) is accessed.

Routine "COMPARE" (sheets 4 & 5) required a certain level of sophistication. Your author finally decided to test first for a "cherry" in wheel 1; continuing for test of wheels 2 (and 3) for cherries only if wheel 1's compare was valid. If the cherry compare failed, the only alternative was to exit, and add the hex codes of the remaining wheel's images to that of wheel 1. Code designation is nominal, since each image corresponds to a given hex code. From label "3BELLS" on, programming was simple, requiring only a sequence in which all possible winning combinations would be tested, with appropriate exits to set up the winning odds for display. The image codes are located in "WHTBL"; addr: '01D8'.

In sheet 5, note the use of RELATIVE INDIRECT ADDRESSING wherever possible. In a tightly organized program, this practice can <u>save</u> considerable user memory.

Starting at line 16 on sheet 5, and on both sheets 6 & 7, appropriate odds numbers are preset into the (winning) odds display message. Once again, the program is tightened in its use of memory, there being no serious time constraints to worry about.

THE PROGRAM: (CONTINUED)

Multiple entry points to (essentially) the same routine are demonstrated on sheet 7, starting at line 10. Routines "ROLL123", "ROLL23", and "ROLL3" are actually a single routine, terminated with a common RETC instruction in line 19. Entry, at addresses '0100', '0106', and '010C', is determined by the current "ROLL" table entry, described previously on page 6-81. The 'rotating wheels" display is controlled by subroutine "DISROL", accessed after each new image is fetched. "DISROL" is located in memory at address '01E9'; its access is via indirect addressed ZBSR instructions. The code '84' in locations '0105','010B', and '0111' points to a 2-byte absolute address ('01E9') at location '0004' (sheet 1). "DISROL" is described near the end of this page.

Subroutine "FETCHWH", accessed by the ROLL routine, generates a random number for indexing into the 16-entry WHEEL TABLE which contains the hex codes for all images in order. Random number generation adds a degree of authenticity to the game, but still remains one of the hardest tasks for a (logical) computer to perform.

Routine "DISMES" is the common subroutine dedicated to all message displays except actual 3-WHEEL ROLL. Timeout and low-order message address constants are preset by the calling program prior to access of this routine. The constant ('01') contained in the COMI instruction (line 13; sheet 9) is deliberate. If the contents of R3 (DSPLDLY) were permitted to decrement to zero, the user would have to depress a HEX or FUNCTION key in order to exit from the display routine.

Routine "SHOWJAK" (sheet 10) is straight forward; it is adequately described in the introduction (above sheet 3 of the listing).

Routine "ZERO" (sheet 11) is necessary in order that UNUSED digits in the current odds display message will be blank, thus that they will not show a residual odds left over from a previous roll sequence.

Routine "DISROL" requires a higher rate of display change (to simulate the rotating wheels) than the other message routine, "DISMES". For this reason, it is streamlined for maximum efficiency, thus permitting the user to exercise considerable program control over the rate at which the wheels are cycled and displayed.

The message table accessed by routine "DISMES" is contained in the INSTRUCTOR 50's SMI memory, starting at location '1780' (sheet 14). This data table (MESTBL) is organized in 8 entries, each 8 bytes in length.

This concludes the comment on program "SLOTMACHIN", A short DIAGNOStic procedure for checkout of the WINNING JACKPOT message is provided on the next page.

JACKPOT MESSAGE DIAGNOSTIC PROCEDURE:

There is only ONE chance in over 65000 that your INSTRUCTOR 50 slot machine game will ever "HIT THE JACKPOT". In order for you to checkout and view the WINNING JACKPOT MESSAGE sequence, perform the following steps:

- 1. Depress MON, BKPT, 6, C, To set a BREAKPOINT (Stop) address and ENT/NXT. at location H'006C' in memory.
- 2. Depress \underline{REG} , \underline{C} , \underline{O} , and To set a START address at location $\underline{ENT/NXT}$.
- 4. Load H'95' codes into the...... Use the INSTRUCTOR 50's "MEMORY DISfollowing locations:

 (1) H'00F9'
 (2) H'00FC'
 (3) H'00FF'

 PLAY & ALTER" mode to load these
 "Bar" codes. Three Bars make a jackpot. You are replacing the current
 "stopped wheel" codes at this time.
- 5. Depress BKPT twice..... to cancel the Breakpoint address.
- 6. Depress $\underline{\text{RUN}}$to execute the program from the Breakpoint without interruption.

The program will display the previous combination of wheels, but then will decode the "winning jackpot" codes due to the alteration performed in step 4. The winning jackpot message, described previously, will be displayed.

NOTES:

ELECTRONIC TRAIN

INTRODUCTION:

The flexible facilities of the INSTRUCTOR 50 are configured this time as an electronic \underline{TRAIN} . Each combination of "engine", "freight cars", and "caboose" is known as a $\underline{CONSIST}$. The operator may select any one of 16 consists for $\underline{display}$ at any given time, simply by toggling a $\underline{selection\ ID}$ into the 4 low -order I/O input switches, then depressing the INT key.

<u>Speed</u> is controlled automatically, under control of the code toggled into the 2nd, 3rd, and 4th high-order I/O input switches. Seven "speeds" may be simulated, from 10 to 80 MPH, in addition to a "stop train" selection.

Direction is controlled via SENS key depression. When the <u>SENS</u> key is depressed, the "train" runs in <u>reverse</u> (left to right) across the HEX DISPLAY. The speed is that determined by the controlling I/O input switches previously described. The "train" runs $\underline{\text{forward}}$ (right to left) when the operator's finger is removed from the $\underline{\text{SENS}}$ key. The $\underline{\text{FLAG}}$ LED is turned on whenever the $\underline{\text{reverse}}$ command is given.

There is one minor "bug" in the software. If the "train" is stopped, it may not be restarted in either direction unless

5. Depress RSTif the train consist is stopped.

NOTE: TURN ON AT LEAST <u>ONE</u> OF THE SPEED CONTROL SWITCHES PRIOR TO DEPRESSING THE RST KEY.

- 6. Toggle Input Switches.....To select any other consist. Try 3, 2, 1, or Ø them all, at different speeds.

THE PROGRAM:

There are 2 major points of interest in program "TRAIN"; these include:

- * Forward and Reverse Motion Control, and
- * Selection & Transfer of the desired Consist into the Switchyard.

FORWARD AND REVERSE MOTION:

Refer to the diagram on the next page, also to the highlights pointed out in the $\underline{\text{Listing}}$. The description is provided on sheet 8.

COMMENT

IST SELECTION OF CONSIST

THE PROGRAM (CONTINUED)

Sheet 8

The steering process for forward and reverse motion control is routine "CHKSENS" (SHEET 2). Immediately after the current consist is displayed, the logical condition of the SENS input is tested. If SENS is active (key down), the BCTR, EQ instruction (line 17) passes execution to a short delay, followed by a 2nd test of the SENS input. This ensures that SENS key depression was deliberate. If the test for SENS activity fails either time, the program assumes that forward motion is desired, and routine "ROLLON" is accessed.

Routine "REVERSE" is initiated with FLAG LED turn-on, followed by a sequenced shift-right of the 8-byte selected consist message. The sequence is graphically illustrated at the middle of the diagram on page 6-91. 8 bytes of memory, labeled "TEMP" provide sufficient space to accomplish the byte shift desired. The first shift, from the Switchyard to 'TEMP', and transfer of 'TEMP7' to 'SWYARD1', is accomplished by process "LOOP1". Transfer of the remaining 7 bytes in 'TEMP', now right shifted, is handled by process "LOOP2". Upon completion of the transfer, program control exits to display the result.

If desired direction is forward, routine "ROLLON" is accessed. Process "REPEAT1" handles the initial 8-byte transfer of the current consist from 'SWYARD' to 'TEMP'. In process 'REPEAT2', the least significant 7 bytes are left-shifted into the 'SWYARD' from 'TEMP'. The remaining byte in TEMP', at location TEMPØ, is then transferred to the least significant location in the 'SWYARD'; this is SWYARD+7. SWYARD+7 corresponds to the rear-most train position in the forward direction. When the transfer is complete, program control exits to display the result.

SELECTION AND TRANSFER OF THE DESIRED CONSIST INTO THE SWITCHYARD:

As noted previously, there are 16 possible train consists which may be selected. From a programmer's viewpoint, these consists are organized in a 16-entry table (SHEETS 4 & 5). Each entry is 8-bytes in length, this being the number of bytes usable in any displayable message.

To select any given entry, the appropriate I/O input switches are positioned to provide a selection I.D., as outlined at the top of sheet 4.

Routine "SWYRDINT" (Switchyard Interrupt) is accessed only when the INT key is depressed. Following an initial process of storing the contents of the current registers and PSW in mainline program use (SHEET 3; LINE 17 AND FOLLOWING), program control transfers to the main part of the interrupt service routine at location ' $\emptyset1\emptyset\emptyset$ ' (SHEET 6). The instructions at addresses '010A'

THE PROGRAM (CONTINUED)

through '0113' convert the input switch pattern into a precise $\frac{index}{index}$ to the desired entry in the Consist Table. This index is then posted as the least significant byte in a 2-byte indirect address field: 'CONADDR', in the INSTRUCTOR 50's SMI memory. Thus, process "LOOP3" can then be executed to make an orderly transfer of the desired 8-byte consist message.

Routine "SWYRDINT" concludes with restoration of previously stored register and PSW contents. The instructions at locations '0134' to '0141' create a 2-instruction subroutine, "RECALL". The purpose of "RECALL" is to permit return to the main program without altering the previously stored condition code. This code, which is used to determine the direction of many branch instructions, can be altered during register restoration. The necessary instructions are found in sheet 7.

Refer to sheet 1 for a description of "speed control".

In lines 1 and 2, the speed input switch pattern is isolated by the microprocessor. Th resultant value is used to condition the Monitor's USRDSP display routine running time constant. When all speed switches are off, the value is zero; this is why the selected consist remains stopped. If 1 or more switches are on, the display "times out" after a short delay. The delay is directly proportional to the value of the switch pattern, as described in the User Operation procedures on sheet 3. After display timeout, program control exits to check direction demands. The consist message is shifted, and control loops back to display the result once again.

The listing of this program is particularly informative in that it provides precise examples of:

- I/O input pattern detection, isolation, and use.(SHEET 1)
- SENSE bit testing and control usage (SHEET 2)
- Multi-byte transfer and shifting techniques (SHEETS 1,2, ε 6)
- Indirect address construction (SHEET 6)
- Data Table organization by multi-byte entry (SHEETS 4 ε 5)
- Index preparation and usage (SHEET 6)
- Register save & restore techniques, including <u>pseudo</u> <u>subroutine construction</u> for Condition Code protection.

 (SHEETS 3,6, & 7)

This concludes the description of program "TRAIN".

INTRODUCTION:

When you listened to the INSTRUCTOR 50 INTRODUCTORY CASSETTE tape, the "electronic music" you heard was generated by executing the program "INSTRUCTOR 50 MUSIC THEME". It is fully documented on these next 3 pages.

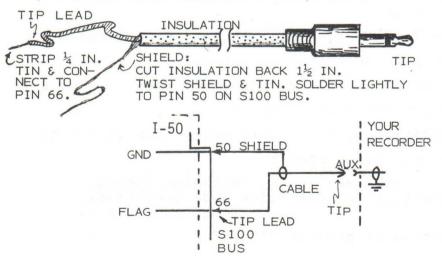

When "source code" is input to an ASSEMBLER, it is necessary to declare the (hex code) value of each symbolic address or operand, PRIOR to its use in the program itself. As explained earlier in this chapter, these declarations are made by implementing $\underline{\text{EQUATE}}$, $\underline{\text{RES}}$, and $\underline{\text{ORG}}$ statements. In line 55 of the listing on the next page, an $\underline{\text{ORG}}$ (address origin) statement defines memory location $\underline{\text{H'0000'}}$ as the program's start address. On the following page, data table "NTAB" is origined at address $\underline{\text{H'100'}}$.

Most of the following page is dedicated to definition of symbolic \underline{EQU} ates in terms of their hex code values.

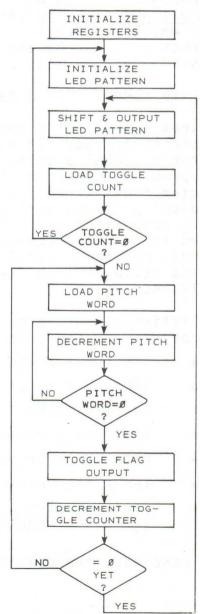

In line 83, a <u>RES</u> statement <u>reserves</u> 1 byte of user memory (at address H'0032') for a symbolic function called "LEDWRD".

A <u>FLOWCHART</u> (to the right) illustrates the overall sequencing of program "INSTRUCTOR 50 MUSIC THEME" as it is executed to play the desired music.

<u>Prior</u> to executing the "music theme" program, prepare an AUDIO CABLE as shown in the diagram below. Then, connect it between the INSTRUCTOR 50 and your cassette recorder or, at your option, to the \underline{AUX} input of an available hi-fi amplifier.

The \underline{source} and \underline{object} \underline{codes} for program "INSTRUCTOR 50 MUSIC THEME" are contained on the following pages.
